How to control the rotational speed of a wind turbine generator?

There are three common methods for controlling the rotational speed of a wind turbine generator. (1), mechanically spilling wind from the blades by changing their pitch angle. (2), use a mechanical brake to stop the turbines rotation at high speeds. Or (3), use some kind of electrical load in the form of a dump load to act as an electrical brake.

Why does a wind turbine generator spin at high speeds?

As an electrically connected load keeps the wind turbine generator within its designed operating range. If a wind turbine generator,(WTG) is allowed to rotate in the wind with the batteries disconnected, it will start spinning at very high speeds because it is operating without any connected load to act as an electrical brake.

How does a wind turbine gearbox work?

The gearbox converts the turning speed of the blades 15 to 20 rotations per minute for a large, one-megawatt turbine into the faster 1,800 revolutions per minute that the generator needs to generate electricity. A gearbox is typically used in a wind turbine to increase rotational speed from a low-speed rotor to a higher speed electrical generator.

Does a wind turbine generator need a controller?

Wind is unpredictable and constantly changing, therefore the electrical output from a wind turbine generator will be a variable voltage and variable frequency (AC types) so the use of a controller for high wind speed protection makes sense.

What happens if a wind turbine generator is not connected?

If a wind turbine generator,(WTG) is allowed to rotate in the wind with the batteries disconnected, it will start spinning at very high speedsbecause it is operating without any connected load to act as an electrical brake. This overspeed condition can cause mechanical damage to the turbine as it could potentially self destruct.

How do type 2 wind turbines work?

While largely relying on the same concepts as fixed-speed wind turbines at lower-than-rated wind speeds, they typically incorporate blade pitch and output power controls to optimize power extraction at higher-than-rated wind speeds. The Type-2 turbines use rotor resistance controlto achieve output power control.

Dump or diversion loads can prevent a wind or hydro generator from spinning too fast once the batteries are fully charged due to the charge controller disconnecting the electrical generator from the attached load.

A modern wind turbine is often equipped with a transformer stepping up the generator terminal voltage, usually a voltage below 1 kV (E.g. 575 or 690 V), to a medium voltage around 20-30 kV, for ...

This article discusses the concept of rotor resistance control, its basis in machine theory and the induction machine equivalent circuit, a few methods of achieving optimal power output based on rotor resistance control, the implementation of the control methods using a modified version of the fixed-speed wind turbine model, and provides a discussion of the results obtained from the ...

So DFIG will change to a multi-phase induction generator with four stator windings and three rotor windings from the normal condition with three stator windings and three rotor windings. The resistance of the split winding is also divided into two parts. The resistance of the un-shorted winding is and the resistance of the new phase is .

The design of this solution consists of a slab foundation for a steel or a concrete tower. It is the most common form of a foundation for wind turbines but yet remains a complex structure. Wind turbine generators (WTG) are becoming more and more powerful and the hub heights are increasing by the day. As a result, the concrete volume can reach ...

Theoretically, notch 1 provides one eighth of the engine/generator power to the traction motors. Since Tractive effort (TE) = Power divided by Speed, a constant level of power provides exponentially decreasing TE as the speed increases. Speed will increase until the TE = the rolling resistance of the engine (or consist).

This paper aims to extract simple formulae for estimating the ground resistance values of wind turbines (WT) installed at terrains that can be modeled by a two-layer soil structure. Several grounding system configurations, applied in construction practice, were used as case studies. Various combinations of soil resistivity values for the upper and the lower layer of a ...
